INTRODUCTION

The Fourteenth Bulletin of North Carolina Morbidity Statistics, covering the calendar year 1945, contains tabulations of the revised group of reportable diseases adopted by the State Board of Health in 1944.

All of the diseases now required to be reported are those for which some specific preventive service is available to the attending physician or the family from the state or local health department.

New presentations of syphilis and tuberculosis morbidity data are presented this year for the first time. Instead of showing only the totals, the various stages of these diseases are enumerated, thereby giving a much more accurate morbidity picture than would be possible otherwise. An analysis of such information for previous years shows that the decline of syphilis that has now occurred without interruption since 1939 has been due chiefly to a decline in the late stages of the disease rather than to a uniform decline in all stages. A study of the 1945 reports of minimal tuberculosis, as compared to those for the far advanced stage, show the ratio for the state as a whole to be approximately one minimal case located for every two far advanced cases. By observing similar ratios for the coming years a measurement can be made of the improvement in the tuberculosis case-finding program. Tuberculosis case reports were considerably increased over the previous year due to inclusion of healed childhood cases under seventeen years of age in the tabulations for the first time and probably also to an increase in case-finding activity.

The most outstanding change in the morbidity picture for 1945 was the increase in diphtheria incidence amounting to 123 per cent over 1944, as compared to a 21 per cent increase for the nation as a whole. A field study showed this increase to have occurred, for the most part, in non-immunized children.

Chancroid showed a decline for the second consecutive year. Endemic typhus fever declined over last year, thereby interrupting a ten-year upward trend. Gonorrhea continued upward reflecting continued improvement in reporting and case-finding. Malaria reports in 1945 were more numerous than in any other year since 1940. Paratyphoid fever and typhoid fever cases reached a new low in 1945. Poliomyelitis cases were somewhat above the average in 1945, the year following our second large epidemic of this disease. Rocky Mountain spotted fever, which showed a significant increase in 1944, remained at approximately the same level in 1945. Undulant fever reports also were approximately equal to those of 1944, which were almost double the 1943 cases.

Changes in the incidence of the other diseases are not of definite significance.

REPORT

The following is a summary of the data reported by the various health departments of the State of North Carolina for the calendar year 1945, covering the calendar year 1945, containing tabulations of the various types of reportable diseases adopted by the State Board of Health in 1944.

All of the diseases now required to be reported are those listed in the following table. A complete list of the diseases which some specific preventive service is available to the community is available from the State or local health department.

New presentations of syphilis and tuberculous meningitis were reported this year for the first time. In the case of syphilis, the various stages of the disease were reported, thereby giving a much more accurate picture than would be possible otherwise. An analysis of such information for previous years shows that the decline of syphilis has been accompanied without interruption since 1939 has been due chiefly to a decline in the late stages of the disease rather than to a uniform decline in all stages. A study of the 1945 reports of syphilis, when compared to those for the two previous years, shows that the ratio for the state as a whole to be approximately one minimal case reported for every two for advanced cases. By observing similar ratios for the preceding years a measurement can be made of the improvement in the tuberculous case-finding program. Tuberculous case reports were considerably increased over the previous year due to inclusion of latent childhood cases under treatment years of age in the tabulations for the first time and perhaps also to an increase in case-finding activity.

The most outstanding change in the morbidity picture for 1945 was the increase in diphtheria incidence amounting to 125 per cent over 1944, as compared to a 21 per cent increase for the nation as a whole. This study shows this increase to have occurred for the most part, in non-immunized children.

Chancroid showed a decline for the second consecutive year. Epidemic typhus fever declined over last year, thereby interrupting a two-year upward trend. Diphtheria continued upward reflecting continued improvement in reporting and case-finding. Measles reports in 1945 were more numerous than in any other year since 1940. Paratyphoid fever and typhoid fever cases reached a new low in 1945. Poliovirus cases were somewhat above the average in 1945, the year following our second large epidemic of this disease. Rocky Mountain spotted fever, which showed a significant increase in 1944, remained at approximately the same level in 1945. Typhoid fever reports also were approximately equal to those of 1944, which were almost double the 1943 cases.

Changes in the incidence of the other diseases are not of definite significance.
